# Nutrition and Food Security Survey in Jaffna District in 2009 

Dr. Renuka Jayatissa<br>Dr. Moazzem Hossaine

## District profile - JAffna

Jaffna district is one of the four districts in the Northern province of Sri Lanka, located at the far north of the province and comprises most of the Jaffna peninsula and several islands.

Map of Sri Lanka showing Jaffna district is given in Figure 1.
Administratively, the district is divided into 15 Divisional Secretary (DS) divisions and 435 Grama Nildhari (GN) divisions. The local government institutions in the province include one Municipal Council (MC) , 1 Urban Councils and 13 Pradeshiya Sabahas ${ }^{1}$.

The district includes a land area of approximately $1,025 \mathrm{sq} . \mathrm{km}$. with a population of 650,720 ( as estimated for 2007). The district has been facing a conflict situation for the past few decades and is undergoing many changes at present.

Health services provided by the state sector, for western type of health services include I Teaching Hospital, 1 Base Hospital, 6 District Hospitals, 6 Peripheral Units, 3 Rural Hospitals 3 other Hospitals and 8 Central Dispensaries / Maternity Homes. Preventive and promotive health services are provided through 11 Health Unit areas with Medical Officers of Health and field staff 2 .

## 1. Methods

### 1.1. Selection of households

A sample of 613 households from the district of Jaffna were included in he study. The sampling frame used for selection of clusters was the most recently available population estimate - the 2001 census from the Sri Lanka Department of Census and Statistics. Clusters were defined at the level of a Grama Niladhari (GN) division. GN divisions were identified using the probability proportional to size technique. Within each cluster, 30 households were identified using a systematic sampling procedure.

Map indicating the selected GN divisions is given in Figure 2.
A household was defined as persons routinely sharing food from the same cooking pot and living in the same compound or physical location. Members of a household need not necessarily be relatives by blood or marriage. All selected households were included in the survey, irrespective of whether there was a child under five.

### 1.2. Composition of the survey teams

Each survey team included three interviewers and one team leader. Co-ordinator was recruited to take the overall responsibility for the conduct of the survey. All team leaders and team

[^0]coordinators were trained by staff from Medical Research Institute (MRI) with experience from past surveys

The three interviewers from the survey team conducted all interviews, averaging seven interviews each, per day. The team leader was responsible for selection of households.

### 1.3. Household survey included several components.

Administration of the questionnaire : A pre tested questionnaire was administered to the head of the household. Where possible, mothers were interviewed to obtain information on child care practices and maternal nutrition. The minimum age of respondents was 15 years.
Anthropometric assessments: All children aged 0 to 59 months, along with their mothers and any pregnant women in the household, were selected for measurement. All measurements were conducted by team leaders, and standardized procedures for measuring the height/length, weight were used (WHO,1995). Anthropometric measurements were made using UNISCALES and UNICEF measuring boards.
For pregnant women, Mid Upper Arm Circumference (MUAC) was measured in addition to height and weight.
Measurement of haemoglobin levels was carried out for all individuals selected for measuresments except children less than six months of age using hemocue method, using capillary blood.

### 1.4. Supervision and quality assurance

Constant supervision and monitoring of all field activities was attempted. Team leaders would monitor interviewers, while team coordinators monitored team leaders as well as the interviewers. Routine field-editing of all questionnaires was conducted by the team leaders.

### 1.5. Data processing and analysis

EPI Info 6.0 software package was used for data management and entry. Data cleaning was carried out in MS Access by sorting records to filter out extreme values and SQL queries to check logical errors. Consistency checks were run to detect and correct data entry errors.

Data analysis was conducted in Anthro and SPSS. Anthro was used to calculate nutrition z-scores for women and children based on the anthropometric measurements, using WHO standards as the reference value..

## 2. Results

A total of 613 households from the Jaffna district was included in the survey. OF them, 85.3 percent were in the rural sector, 14.7 percent in the urban sector.

Of the total 2776 individuals who were usually resident in the selected households, 763 ( 27.5 percent) were women aged between 15.0 and 49.9 years. Seventeen percent ( $\mathrm{n}=4799$ ) of the total population were Children aged between 5.0 and 14.9 years constituted 14.9 percent of the population and 10.3 percent were children aged less than 5 years. Of the population , 6.4 percent were children aged between 2.0-4.9 years,

### 2.1. Nutritional status of children

### 2.1.1 Prevalence of malnutrition

The three indices of physical growth that describe the nutritional status of children according to WHO growth standards (WHO, 2006) are : Height-for-age, Weight-for-height and Weight-for-age. Each of the four nutritional status indicators expressed in terms of standard deviations from the median (Z-scores) of the reference population was used to assess the prevalence of stunting ( height for age <-2SD), wasting ( weight for height <-2SD), underweight ( weight for age <-2SD ) and overweight (weight for height more than $+2 S D)$.

A total of 270 children under five years were i included in the survey. As shown in Table 1, among all children in the age group $0-59$ months, 15.2 percent were stunted, 9.6 percent wasted and 14.4 percent were underweight. Severe stunting was seen among 1.9. percent of the total group, with the comparable figures for severe wasting and severe underweight being 0.7 percent and 1.5 percent respectively. There were only 0.7 percent of children with weight for height values more than +2 SD .

Comparisons made between sub groups are based on relatively low numbers within each such group, hence have to be interpreted with caution.

The prevalence of stunting ( height for age <-2 SD) was highest during the 12-23 months of age . Prevalence of underweight was highest in the fifth year of life.. The percentage of children with stunting and wasting were higher among males compared to females. Prevalence of severe stunting, was highest in the fourth year of life ( 4.3 percent), among males ( 2.4 percent),

Table 1 Prevalence of malnutrition: stunting, wasting, overweight and underweight by background characteristics

### 2.1. 2. Anaemia in children

The haemoglobin levels of 262 children in the age group 6-59 months were assessed using the 'haemocue 'method (cut off point - $\mathrm{Hb}<11.0 \mathrm{gms} \%$ ). As shown in Table 2, the prevalence of anaemia in this group was 34.0 percent, with the highest percentage during the early half of infancy ( 46.7 percent), and
declining with increasing age, with the 48-59 months age group showing the lowest prevalence (17.4 percent). Male children showed a higher prevalence 32.0 percent) than females(17.0).
There was no consistent pattern in the prevalence of anaemia with increasing maternal education and indicators of income and wealth.

Table 2 Prevalence of anaemia among children 6-59 months of age by background characteristics

| Background characteristic | \% of children with Anaemia ( $\mathrm{Hb}<11.0 \mathrm{~g} / \mathrm{dl})^{*}$ | Number of Children who were investigated for Hb |

| Richest | 23.1 | 13 |
| Overall | 34.0 | 262 |

### 2.1.3. Birth weight

The birth weights were obtained form the Child Health Development Records (CHDRs). This study included children born within the 5 years preceding the survey. Considering the newborns with a birth weight of less than 2500 grams as being low birth weight (LBW), the overall prevalence was 16.6 percent ( Table 3 ) . Birth weight distribution by the current age of the child enables comparison of prevalence of LBW among different birth cohorts. There is no definite pattern observed except that the cohort aged between 36-47 months at the time of the study had the highest prevalence of LBW of 21.1 percent.

The prevalence was higher among female newborns than males.. There is a decline in the prevalence with increasing levels of mother's education and with increasing income levels and wealth quintiles.

Mean birth weight for the total group was $2.95 \pm 0.52 \mathrm{~kg}$ with no clear pattern observed between age groups, districts, and maternal educational levels. However, an upward trend was observed in relation to increasing income levels and higher levels of wealth quintiles.

Table 3 Prevalence of low birth weight, and mean birth weight among children born in the 5 years preceding the survey, by background characteristics

| Background characteristic | Birth Weight |  |  |  | Number of children |
| :---: | :---: | :---: | :---: | :---: | :---: |

### 2.2. Nutritional status of women of 15-49 years

## 2..2.1 Non pregnant women ( using Body Mass Index )

A total of 261 non-pregnant women aged between 15 to 49 years, and with a child under 5 years age were included in the assessment of body mass index. As shown in Table 4., of the total sample of non-pregnant women, 20.5 percent had BMI less than 18.5, 15.5 percent with values between 25 and 29 (overweight) and 6.4 percent, with BMI values 30 or above (obese).

The prevalence of underweight (BMI less than 18.5) was highest in the 20-27 age group ( 27.1 percent) with a decline with increasing age. There was a declining pattern in the prevalence with higher wealth quintiles. The prevalence of overweight and obesity showed an increase with higher income and wealth index.

Of all non-pregnant women studied, 21.9 percent were either overweight or obese. This percentage was higher in the older age groups,.

Table 4 Distribution of non-pregnant women 15-49 years by BMI levels, by background characteristics

|  | BMI category (\%) |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |

| Sector |  |  |  |  |  |

### 2.2.2. Pregnant women ( using Mid Upper Arm Circumference ( MUAC)

Nutritional status of 27 pregnant women were assessed using MUAC. This assessment indicated that 14.8 percent of this group were undernourished.

### 2.2.3 Anaemia in women

Three groups of women were included in this component of the study : I). pregnant women (27) ii.) lactating women (57) iii.) all I non pregnant women including lactating women (218).

## Pregnant women

As shown in Table 5, overall prevalence of anaemia among this group was 14.8 percent. Comparisons between subgroups require cautious interpretation due to limited number of pregnant women included in each of the sub-categories.

## Lactating women

Among lactating women, the overall prevalence was 35.1 percent, much higher than among the pregnant women.

## All non-pregnant women

The overall prevalence among this group was 35.3 percent .

Table 5 Prevalence of Anaemia*, among i) pregnant women, ii). lactating women and iii). All nonpregnant women by background characteristics

## All tables in this section are given in annex 1

## II

### 2.3. Childhood Illnesses

Diarrhoea and respiratory infections are the two common illnesses that lead to increased morbidity and mortality among children under 5 years. The present study sought information from respondents related to the occurrence of these two illnesses during the two weeks preceding the interview.

### 2.3.1. Respiratory illness

Respondents were asked whether their children less than five years of age had one or more symptoms related to respiratory illness (cough, rapid or difficult breathing) during the period of 2 weeks preceding the survey. A child who was having cough with rapid or difficult breathing, was identified as having had symptoms of respiratory illness. Among the total group, 22.2 percent reported to have had symptoms related to respiratory illness during the specified period (Table A 1).

### 2.3.2. Diarrhoea

The respondents were asked whether their children under five years had experienced an episode of diarrhea during the two weeks preceding the survey. (Diarrhoea was defined as three or more loose or watery stools per day or blood in stool). If the child had diarrhea, information on giving oral dehydration fluid using the packet 'Jeewani' during the episode of diarrhoea, was inquired into. Of the total group, 5.2 percent of children who reported to have had diarrhea during the specified period. Of them, 28.6 percent were given "Jeewani" .

### 2.3. Dietary intake and feeding practices

### 2.3.1.Breastfeeding practices

Percentage of children less than 24 months years of age who were ever breastfed, currently breastfed and started breastfeeding within one hour / one day of birth are given in Table A 2. All children were 'ever breastfed'. Of them, 91.3 percent were breast fed within the first hour of birth and the same percentaget were currently breast fed , given breast milk in the previous 24 hours .

### 2.3.2. Complementary feeding and bottle-feeding practices

As shown in Table A 2, 88.9 percent of all children 6-8 months were given breast milk and solid / semi solid foods and 42.7 percent of children under 24 months had been bottle fed.

### 2.3.3. Food Consumption among children in the age group 6-59 months

Food consumption pattern was based on the information about the food items given to children aged 6 59 months on the day preceding the interview. Ten different food items were included in this analysis.

For the total sample, 84.9 percent of the children were given grains/roots/tubers, while $50-60$ percent were given fruits and vegetables, and meat fish/ poultry/ organ meats. Proportions of children who received eggs was comparatively high ( 57.6 percent) and the consumption of dairy products was low( 26.2 percent). Foods cooked with oil or fat were given to 52.0 percent of children and 46.5 percent were given fortified food (commercially available cereals), and 80.1 percent or were given sugary food (chocolates, sweets, candies, cakes, biscuits etc.) .

### 2.3.4.Dietary diversity

Dietary diversity is based on the premise that more diverse diets are more likely to provide adequate levels of a range of nutrients.

## Individual dietary diversity score for children aged 6-59 months

In this study, individual dietary diversity score for children aged 6 - 59 months was assessed. ( according to FANTA ${ }^{3}$. As shown in Table A 4, for all children in this age group, the IDDS was 4.7 ( $\mathrm{SD}=1.9$ ) .

The dietary diversity score of children aged 6-59 in the households belonging to the highest wealth quintile was used as a "target to be achieved" based on the assumption that poorer households will diversify their food consumption practices as incomes rise, and thereby attempting to follow the consumption pattern of wealthier households. Table A 4 shows the IDDS among children in the highest wealth quintile was 5.5 . Based on this value, the percentage of children yet to achieve the target was assessed. This percentage was 66.4 for the total sample. The percentage decreased with increasing income categories and wealth quintiles.

Information on Minimum meal frequency, minimum dietary diversity and minimum acceptable diet for children aged 6-23 months are given in Table A 5 .

### 2.4. Care Practices

Care practices were studied in relation to activities on early childhood development including promoting early learning at household level, practices related to play activities, early childhood education, school enrolment. The age group to be included in the different components in the study of care practices varied, depending on the relevance.

### 2.4.1. Promoting early learning at household level

As shown in Table A 6, the average number of education related activities' undertaken by the children was 4.9. For 75.0 percent of children, an adult was engaged in more than three activities that promoted early learning, during the 3 days preceding the survey. Considering the children under 5 years of age, 26.3 percent were looked after by a child under the age of 10 years, during the week preceding the interview.

### 2.4.2. Childhood education

As shown in Table A 7, of the children aged 36-59 months, 61 percent had attended an early childhood educational programme and 99.9 percent of the children who have completed 5 years by 31 st January 2009 were enrolled in grade 1 and1the same percentage of I children $5-10$ years of age were attending Primary School ( Table A 8 ).
Information related to play items used by the children and 'child labour are given in Table A9 and A 10 respectively..

### 2.5. Use of health services

### 2.5.1. Attendance at Child Welfare Clinic

[^1]As shown in Table A 11, 86.5 percent of the children under 5 years had received care at a Child Welfare Clinic (CWC) and 90.4 percent of the children had their Child Health Development Records (CHDRs) with them at the time of interview. Of the mothers who attended the child welfare clinics, 88.6, 88.8 and 82.4 percent received advice on growth, nutrition and early childhood development respectively. Of this group, 14.8 percent of children aged $6-59$ months had received at least one packet of thriposha in the previous month.

### 2.5.2. Vitamin A supplementation for children

Of the group, 81.1 percent of children who had completed 9 months of age had received a mega dose of vitamin with the percentage of children who received a vitamin A mega dose at 18 months, 36 months being 78.8 and 74.7 percent respectively. Considering all children aged 36 months and over 70.8 percent had been given 3 mega doses of Vitamin A (Table A 13).
Of the mothers who attended the ANC, 89.5 percent of mothers received iron tablets of whom 72.2. percent took the tablets daily.

### 2.5.3. Source of medical care for common childhood illnesses

Source of medical care for those children who reported diarrhoea / respiratory symptoms within the 2 weeks preceding the interview was considered under services provided by the government sector, private sector and other sectors. As shown in Table A 13, 50.9 percent of the total group used services from the government sector, 47.4 percent from the private sector and 1.8 percent from other sectors.

### 2.5.4. Use of services at antenatal clinics

A total of 87.0 percent of the pregnant mothers had attended antenatal clinics regularly as shown in Table A 14 . Among the 89.5 percent of pregnant mothers who received iron supplement, 72.2.percent took the supplement regularly.

### 2.5.5. Food and nutrient supplementation for women

The two main nutrition supplementation programmes aimed at pregnant women are the provision of a food basket ("poshana malla" ) through the Samurdhi programme implemented by the : Ministry of Samurdhi and Poverty Alleviation and the Thriposha programme implemented by the Ministry of Health care and Nutrition. Of all pregnant mothers, 69.6 percent received Thriposaha and 66.7 percent had received "poshana malla" (Table A 15).

Of the lactating mothers with a child under 6 months of age, 71.4 percent had received "thriposha" (Table A 16) and vitamin A mega dose has been given to 95.2 percent, after childbirth.

### 2.5.6. Samurdhi beneficiaries

In the households included in the study, there were a total of 201 non pregnant, non lactating women in the age group 15-49 years. Of this group, 42.3 percent received Samurdhi benefits, being members of households that were beneficiaries under the Samurdhi programme. ( Table A 16).

Percentage beneficiaries among the pregnant women and lactating women were 29.6 percent and 40.0 percent respectively.

### 2.6. Water and Sanitation

### 2.6.1. Use of improved water sources

As shown in Table A 17, 87.3 percent of the households had improved sources of water. There was no consistent pattern showing an association with income or wealth quintile.
Of all households, 59.1 percent used one of the appropriate water treatment methods to treat their drinking water with boiling being the most frequently used method, practiced by 34.4 percent of the households included in the study (Table A 18). The percentage of households that used boiling as a method of making water safe, increased marginally from the lowest wealth quintile to the highest. In some households, more than one method was used

### 2.6.2. Use of sanitary means of excreta disposal

Use of flush toilets connected to sewage systems, or septic tanks was considered as sanitary means of excreta disposal. As shown in Table A 19, the percentage of households using sanitary means of excreta disposal was 85.0 percent.

### 2.6.3. Use of improved water sources and sanitary means of excreta disposal

Table A 20 shows the distribution of households that use both improved sources of drinking water and sanitary means of excreta disposal. For the district sample, . 73.6 percent of households reported using both improved water source and sanitary means of excreta disposal. The percentage of households that had both facilities increased with increasing levels of wealth quintiles.

Information on the time consumed to collect water and the person collecting water are given in Tables A 21 and A 22 respectively.

### 2.7. Food Security and Coping Strategies

### 2.7.1. Household food consumption

The food items consumed by households were grouped into 11 categories based on the FAO classification of food groups with some modifications to include coconut and sugar separately. These food groups were used in assessing the food consumption pattern as shown in Tables A 23 and A 24.

Table A 23 provides information on food items consumed within 24 hours preceding the survey. Consumption of rice and rice products, coconuts and sugar ranged from 95-100 percent and consistent across all sub groups studied. Bread and wheat products were consumed by 23.1 percent 012.5 percent. with only 7.8 percent of households having consumed fruits.

The percentages of households that consumed milk and milk products was 12.7. Consumption of oils and fats were 59.9 percent.

Information on the consumption of different foods for at least 5 days during the week preceding the survey is shown in Table A 24. This information indicated the consistency of consumption of the foods and shows important differences from the Table A. 23, which focused on the consumption pattern during the 24 hours preceding the survey.

Similar to the 24 -hour consumption pattern, rice, coconut and sugar were consumed by more than 95 percent of the households. However, the consumption of food groups such as bread and wheat products, nuts and pulses, fruits, meat/poultry/fish and dry fish, eggs, and milk/dairy products were markedly lower during the 7 -day period.

Table A 25 provides information on the household members who consume three or more main meals a day.

### 2.7.2. Household dietary diversity

Household dietary diversity score (HDDS) is a proxy measure of households consuming a variety of food indicating a nutritionally 'satisfactory' diet and the method used to make this assessment is given in Table A 26 . This table indicates that the mean HDDS for the total group was 7.2 (SD 1.9). The values ranged from 7.0. in the lowest wealth quintile to 8.3 n the highest.

The HDDS obtained by the households in the highest wealth quintile category (8.3) was taken as the 'target ' to be achieved and the percentage of households yet to achieve the target was calculated. For the total sample, the percentage of households yet to achieve the target was 77.2 .The percentage showed a consistent decline with increasing income and wealth quintiles.

### 2.7.3. Expenditure on food and other goods and services

Study of broad categories under which household expenditure for a one-month period showed that considering all households included in the study, 73.3 percent of the total household monthly income was spent on food, and 8.4 percent on other goods and services (Table A 27).

Food groups by source is given in Table A 28. Food availability at household, food stocks and food aid are given in tables A 2930 and 31 respectively.

### 2.7.4. Coping Strategies

During the periods when there were limitations in food availability, different coping strategies were adopted by households (Table A 32 ). Use of such strategies during the month preceding the survey was studied paying attention to the frequency of practice. Of the total number of households, 47.8 percent had adopted one or more coping strategies. Of them, more of the households adopted food related coping strategies compared to non-food coping strategies.

The common strategies adopted were: to rely on less preferred food ( 33.9 percent) and purchased food on credit ( 32.4 percent). Approximately, $30-35$ percent, had borrowed food or reduced meal size. The main non-food strategies adopted were : borrowing money from relatives/neighbours ( 34.3 percent) and pawning jewellary (32.8 percent.

The distribution of the households that adopted a specific food-related coping strategy by background characteristics is shown in Table A 33. The number of households in the sub categories are small, hence the limitations in drawing conclusions

Taking loans is a commonly adopted strategy to cope with difficult situations, whether it be food related or not. As shown in Table A 34, 49.1 percent of households had taken loans within the preceding month which were used for: purchase food ( 53.3 percent), and for medical costs( 23.7 percent).

### 2.7.5. Food insecurity

A state of food insecurity exists when nutritionally adequate and safe foods are not readily available or there is inability to acquire acceptable foods. In this study, food insecurity levels were determined according to the method described by the World Food Programme (WFP), given in annex $2 .$.

### 2.7.5.1. Household food consumption adequacy score (HFCAS)

As shown in Table A 35, the mean HFCAS for all households was 65.6(SD=16.9). The scores differed between sectors, higher in the urban sector, 70.5 compared to the rural sector, 64.7. Study of HFCAS categories indicate that 0.3 percent of the households had poor food consumption, 2.3 percent were borderline and 97.4 percent, had adequate food consumption. .

### 2.7.5.2. Food insecurity categories

Food insecurity levels obtained by cross-tabulating food access categories ( as indicated by percentage expenditure on food) and food consumption categories for households with a child aged less than 5 years ( $\mathrm{n}=282$ ) are presented in Table 36. Of these households, 0.8 percent were found to be 'severely food insecure' with comparable percentages for 'moderately insecure' and 'secure' were 22.5 and 76.7 percent respectively.

In interpreting food insecurity, the two categories, moderately and severely food insecure categories were considered together. The percentage of food insecure households in the urban sector(84.0) was lower compared to the rural sector ( 75.8).( Table A 37).

Considering the key socio-economic indicators included in this study, the marked influences such indicators have on food insecurity is clearly shown. There seems to be an upward trend in the percentage of food secure households, with increasing level of education of the head of the household and increasing income levels and wealth quintiles. However, these observations have to be interpreted with caution as numbers in some of these groups are limited.

## ANNEX 1

## Childhood Illnesses

## ANNEX 2

The steps followed in estimating levels of food insecurity were as follows:
Step1: Calculate a household food consumption adequacy score (HFCAS) based on food groups consumed during 1 week prior to survey, grouped into 3 categories as described in footnote ${ }^{4}$.
Step 2: Estimating the expenditure on food as a percentage of the total household expenditure, and categorizing the households into 3 groups indicating different levels of food access (<75 percent - good; 75t o 90 percent - average and $>90$ percent - poor food access).
Step 3: Cross-tabulation between food consumption categories and food access categories.

Food insecurity levels were assessed in accordance with the classification given in Figure X .
Figure X . Assessment of food insecurity levels

| Food consumption | Poor | Borderline | Adequate |
| :--- | :---: | :---: | :---: |

${ }^{4}$ Eight food groups were used to calculate the Food consumption adequacy score.
Food group

## Food times

1. Staple foods (starches)

Rice, bread / chapti /roti
2. Pulses/legumes

Pulses
3. Vegetables vegetables (including leaves)
4. Fruits
5. Animal protein
fruits
6. Sugar
7. Dairy products
sugar/ jaggary
8. Oillfats

Curd, milk (liquid or powder)
palm oil, vegetable oil, fats, coconut products (dried copra)
The number of days the food items were consumed during the previous week was summed for the food items in each of the 8 food groups. If the total sum of the number of days of the separate items in a food group was higher than 7 days, the sum is converted to 7. Thus, the maximum score for each food group is 7 days. The food score of each household is calculated as follows:

Simple food score $=2$ * staple +3 * pulses $+1^{*}$ vegetables $+1^{*}$ fruit +4 * animal protein +0.5 * sugar +3 * dairy +0.5 * oil The households were grouped according to their scores by applying the standard cut-offs as follows:

- Poor food consumption: simple food score is $0-21$
- Borderline food consumption: simple food score is 21.01 - 35
- Adequate food consumption: simple food score is 35.01 and higher

| Food access |  |  |  |
| :--- | :---: | :---: | :---: |
| Poor | Severely food insecure | Severely food insecure | Moderately food insecure |
| Average | Severely food insecure | Moderately food insecure | Food Secure |
| Good | Moderately food <br> insecure | Food Secure | Food Secure |

${ }^{1}$ Eight food groups were used to calculate the Food consumption adequacy score.
